Field of the Invention

[0002] The present invention relates to methods and
15 apparatus for intraluminally forming and securing gastrointestinal ("GI") tissue folds. More particularly, the present invention relates to methods and apparatus for reducing the effective cross-sectional area of a gastrointestinal lumen.

Background of the Invention

[0003] Morbid obesity is a serious medical condition pervasive in the United States and other countries. Its complications include hypertension, diabetes, coronary artery disease, stroke, congestive heart failure, multiple orthopedic problems and pulmonary insufficiency with markedly decreased life expectancy.

[0004] Several surgical techniques have been developed to treat morbid obesity, e.g., bypassing an absorptive surface of the small intestine, or reducing the stomach size. These procedures are difficult to perform in morbidly obese patients because it is often difficult to gain access to the digestive organs. In particular, the layers of fat encountered in morbidly obese patients make difficult direct exposure of the digestive organs with a wound retractor, and standard laparoscopic trocars may be of inadequate length.

[0005] In addition, previously known open surgical procedures may present numerous life-threatening post-operative complications, and may cause atypical diarrhea, electrolytic imbalance, unpredictable weight loss and reflux of nutritious chyme proximal to the site of the anastomosis. Further, the sutures or staples that are often used in these surgical procedures may require extensive training by the clinician to achieve competent use, and may concentrate significant force over a small surface area of the tissue, thereby potentially causing the suture or staple to tear through the tissue.

[0006] The gastrointestinal lumen includes four tissue layers, wherein the mucosa layer is the top tissue layer followed by connective tissue, the muscularis layer and the serosa layer. One problem with conventional gastrointestinal reduction systems is that the anchors (or staples) must engage at least the muscularis tissue

layer in order to provide a proper foundation. In other words, the mucosa and connective tissue layers typically are not strong enough to sustain the tensile loads imposed by normal movement of the stomach wall during ingestion and processing of food. In particular, these layers tend to stretch elastically rather than firmly hold the anchors (or staples) in position, and accordingly, the more rigid muscularis and/or serosa layer must be engaged. This problem of capturing the muscularis or serosa layers becomes particularly acute where it is desired to place an anchor or other apparatus transesophageally rather than intraoperatively, since care must be taken in piercing the tough stomach wall not to inadvertently puncture adjacent tissue or organs.

15 [0007] In view of the aforementioned limitations, it would be desirable to provide methods and apparatus for forming gastrointestinal tissue folds that achieve gastric reduction by reconfiguring the GI lumen of a patient.

20 [0008] It would be desirable to provide methods and apparatus for forming gastrointestinal tissue folds using anchors that can be reconfigured from a reduced delivery profile to an expanded deployed profile.

[0009] It also would be desirable to provide methods and apparatus for forming gastrointestinal tissue folds, wherein an anchor assembly is extended across stomach folds that include the muscularis and serosa tissue layers.

25 [0010] It further would be desirable to provide methods and apparatus for forming gastrointestinal tissue folds, wherein the anchor assembly is deployed in a manner that reduces a possibility of injuring neighboring organs.

30

[0011] It still further would be desirable to provide methods and apparatus for forming gastrointestinal tissue folds, wherein reduced training of a clinician is required to achieve competent use of the anchor assembly.

5

Summary of the Invention

[0012] In view of the foregoing, it is an object of the present invention to provide methods and apparatus for forming gastrointestinal tissue folds that achieve gastric reduction by reconfiguring the GI lumen of a patient.

[0013] It is another object of the present invention to provide methods and apparatus for forming gastrointestinal tissue folds using anchors that can be reconfigured from a reduced delivery profile to an expanded deployed profile.

[0014] It is an additional object of this invention to provide methods and apparatus for forming gastrointestinal tissue folds in which an anchor assembly is extended across stomach folds that include the muscularis and serosa tissue layers.

[0015] It is a further object of the present invention to provide methods and apparatus for forming gastrointestinal tissue folds, wherein the anchor assembly is deployed in a manner that reduces a possibility of injuring neighboring organs.

[0016] It is yet another object to provide methods and apparatus for forming gastrointestinal tissue folds, wherein reduced training of a clinician is required to achieve competent use of the anchor assembly.

[0017] These and other objects of the present invention are accomplished by providing a catheter configured for advancement into a patient's gastrointestinal lumen to form a gastrointestinal tissue

fold. In one preferred embodiment, the catheter has a distal region including a tissue grabbing assembly adapted to engage and stretch a portion of the tissue wall of the GI lumen at a first tissue contact point. A
5 second tissue contact point is then established with the tissue wall at a location initially proximal of, or in line with, the first tissue contact point. The tissue engaged by the tissue grabbing assembly then is moved to a position proximal of the second tissue contact point to
10 form a tissue fold, and an anchor assembly may be delivered across the tissue fold. Preferably, delivery of the anchor assembly across the tissue fold includes delivering the anchor assembly across the muscularis and serosa layers of the tissue wall.

15 [0018] In a preferred embodiment, the tissue grabbing assembly is carried on a first flexible tube associated with the distal region of the catheter, and the anchor assembly is delivered by an anchor delivery system disposed within a second flexible tube associated with
20 the distal region of the catheter. The tissue grabbing assembly may comprise any of a number of mechanisms configured to engage the tissue wall, including a pair of jaws configured to move between open and closed positions, a plurality of linearly translating barbs, or
25 one or more needles or hooks. The first tissue contact point may be moved from a tissue engagement position distal to, or in line with, the second tissue contact point, to the tissue folding position by any of a number of mechanisms, including a hinge assembly or a treadmill
30 assembly.

[0019] More preferably, the distal region of the catheter includes a bendable section that permits the first tissue contact point to be positioned relative to the second tissue contact point so that the tissue fold

is oriented substantially perpendicular to the anchor delivery system. In this manner, the anchor delivery system, when deployed, pierces the tissue fold and exits into the interior of the GI lumen, rather than the exterior of the tissue wall, thereby reducing a risk of injury to adjacent organs.

[0020] The anchor assembly delivery system of the present invention preferably comprises a needle or obturator adapted to pierce the tissue fold and deliver an anchor assembly. In one preferred embodiment, the anchor assembly comprises a pair of rod-like anchors that are delivered through a needle in a reduced delivery profile, wherein the longitudinal axis of the rods is substantially parallel to the longitudinal axis of the needle. Once ejected from the needle, the rods rotate about 90 degrees to engage the tissue. In other embodiments, the anchor assembly may comprise anchors of various shaped delivered, for example, over the exterior of an obturator.

[0021] Methods of using the apparatus of the present invention also are provided.

Brief Description of the Drawings

[0022] The above and other objects and advantages of the present invention will be apparent upon consideration of the following detailed description, taken in
5 conjunction with the accompanying drawings, in which like reference characters refer to like parts throughout, and in which:

[0023] FIGS. 1A and 1B are, respectively, a side view and detail view of apparatus of the present invention for
10 forming a gastrointestinal fold in accordance with the principles of the present invention;

[0024] FIGS. 2A and 2B are side-sectional views of a tissue grabbing assembly suitable for use with the apparatus of FIGS. 1;

15 [0025] FIGS. 3A-3E are side views illustrating a method of using the apparatus of FIGS. 1 to form a gastrointestinal fold;

[0026] FIGS. 4A-4C are side-sectional views of an anchor assembly and delivery system suitable for use with
20 apparatus of the present invention;

[0027] FIGS. 5A and 5B are side-sectional views of another anchor assembly suitable for use with apparatus of the present invention;

[0028] FIGS. 6A and 6B are side-sectional views of
25 another alternative anchor assembly suitable for use with apparatus of the present invention;

[0029] FIGS. 7A-7C are, respectively, a schematic side-sectional view of a unidirectionally adjustable anchor assembly suitable for use with apparatus of the
30 present invention, schematic side-sectional views of alternative techniques for fixing the distal anchor of the assembly, and a cross-sectional view of the proximal anchor taken along section line A--A of FIG. 7A;

[0030] FIGS. 8A and 8B are schematic cross-sectional views illustrating the unidirectional adjustment capability of the anchor assembly of FIGS. 7;

[0031] FIGS. 9A-9C are schematic cross-sectional views of alternative embodiments of the proximal anchor of the anchor assembly of FIGS. 7;

[0032] FIGS. 10A and 10B are schematic cross-sectional views of an alternative unidirectionally adjustable anchor assembly suitable for use with apparatus of the present invention;

[0033] FIGS. 11A-11C are, respectively, a schematic side-view of another alternative unidirectionally adjustable anchor assembly suitable for use with the present invention, and cross-sectional views of the same taken along section line B--B of FIG. 11A;

[0034] FIG. 12 is a schematic cross-sectional view of an alternative unidirectionally adjustable anchor assembly comprising pivoting paddles;

[0035] FIG. 13 is a schematic cross-sectional view of an alternative unidirectionally adjustable anchor assembly comprising spring material;

[0036] FIGS. 14A-14B are schematic side-sectional views of alternative unidirectionally adjustable anchor assemblies comprising one-way valves;

[0037] FIGS. 15A-15C are side-sectional and detail views of alternative unidirectionally adjustable anchor assemblies comprising slipknots;

[0038] FIGS. 16A-16C are, respectively, a schematic side-sectional view of a bi-directionally adjustable anchor assembly comprising a locking mechanism, and cross-sectional views of the same taken along section line C--C of FIG. 16A;

[0039] FIGS. 17A-17D are perspective views of alternative anchors suitable for use with the anchor assemblies of the present invention;

[0040] FIGS. 18A-18D are side views of alternative apparatus for forming a gastrointestinal fold;

[0041] FIG. 19 is a cross-sectional view of the apparatus of FIGS. 18A-18D;

[0042] FIGS. 20A-20D are side views of further alternative apparatus for forming a gastrointestinal tissue fold in accordance with the principles of the present invention;

[0043] FIGS. 21A-21G are schematic side-sectional views of an anchor delivery system adapted for use with the adjustable anchor assemblies of FIGS. 7-17, illustrating a method of delivering the unidirectionally adjustable anchor assembly of FIGS. 7 across a tissue fold;

[0044] FIGS. 22A and 22B are, respectively, a schematic side-view, partially in section, and an end-view of an alternative anchor delivery system adapted for use with the adjustable anchor assemblies of FIGS. 7-17, wherein the proximal anchor is disposed within a separate delivery tube;

[0045] FIG. 23 is a schematic side-sectional view of an alternative anchor delivery system adapted for use with the adjustable anchor assemblies of FIGS. 7-17, wherein both the proximal and distal anchors are loaded within the needle; and

[0046] FIG. 24 is a schematic side-sectional view of an alternative embodiment of the anchor delivery system of FIG. 23 comprising motion limitation apparatus.

Detailed Description of the Invention

[0047] In accordance with the principles of the present invention, methods and apparatus are provided for intraluminally forming and securing gastrointestinal ("GI") tissue folds, for example, to reduce the effective cross-sectional area of a GI lumen. These methods and apparatus may be used to treat obesity by approximating the walls of a gastrointestinal lumen to narrow the lumen, thus reducing the area for absorption in the stomach or intestines. More particularly, the present invention involves endoscopic apparatus that engages a tissue wall of the gastrointestinal lumen, creates a tissue fold and disposes an anchor assembly through the tissue fold. Preferably, the anchor assembly is disposed through the muscularis and/or serosa layers of the gastrointestinal lumen. In operation, a distal tip of the probe engages the tissue and then moves the engaged tissue to a proximal position relative to the catheter tip, thereby providing a substantially uniform plication of predetermined size.

[0048] Formation of a tissue fold preferably is accomplished using two tissue contact points that are separated by a linear or curvilinear distance, wherein the separation distance between the tissue contact points affects the length and/or depth of the fold. In operation, a tissue grabbing assembly engages the tissue wall in its normal state (i.e., non-folded and substantially flat), thus providing a first tissue contact point. The first tissue contact point then is moved to a position proximal of a second tissue contact point to form the tissue fold. An anchor assembly then may be extended across the tissue fold at the second tissue contact point.

[0049] More preferably, the first tissue contact point is used to engage and then stretch or rotate the tissue

wall over the second tissue contact point to form the tissue fold. The tissue fold is then articulated to a position so that a portion of the tissue fold overlies the second tissue contact point at an orientation that is substantially normal to the tissue fold. An anchor then is delivered across the tissue fold at or near the second tissue contact point.

[0050] Referring to FIGS. 1, apparatus 10 of the present invention comprises torqueable catheter 11 having distal region 12 from which first and second interconnected flexible tubes 13 and 14 extend, and proximal region 15 having handle 16 and actuator 17. Catheter 11 is configured for insertion through a patient's mouth and esophagus into the gastrointestinal lumen. Tissue grabbing assembly 18 is disposed on the distal end of flexible tube 13, and is coupled to actuator 17 via control wire 19 that extends through flexible tube 13.

[0051] As better illustrated in FIG. 1B, flexible tubes 13 and 14 are connected via hinge assembly 20 that comprises link 21 attached to flexible tube 13 at pivot point 22 and attached to flexible tube 14 at pivot point 23. Hinge assembly 20 prevents tissue grabbing assembly 18 from moving more than a predetermined distance relative to distal end 24 of flexible tube 14.

[0052] Still referring to FIG. 1B, flexible tubes 13 and 14 preferably include bendable sections 25 and 26, respectively, that comprise a plurality of through-wall slots 27 to enhance flexibility of the tube. Preferably, flexible tubes 13 and 14 are made from stainless steel with an etched or laser-cut slot pattern. More preferably, the slot pattern is a sinusoidal repeating pattern of slots perpendicular to the longitudinal axis of tubes 13 and 14.

[0053] Referring to FIGS. 2A and 2B, tissue grabbing assembly 18 comprises pair of jaws 28a, 28b arranged to rotate about pivot point 29 between an open configuration (FIG. 2A) and a closed configuration (FIG. 2B). Control wire 19 is coupled via pivot point 30 to arms 31a and 31b. Arms 31a and 31b are in turn pivotally coupled to jaws 28a and 28b, respectively, at pivot points 32a and 32b. Each of jaws 28a and 28b preferably includes sharpened teeth 33 disposed near its distal ends to facilitate grasping of the tissue wall of the GI lumen.

[0054] Control wire 19 is coupled to actuator 17 of handle 16 so that translation of the wire within flexible tube 13 causes the jaws to open or close. In particular, urging control wire distally (as indicated by arrow A in FIG. 2A) moves pivot point 30 distally, thereby forcing the jaws to open. Urging control wire 19 proximally (as indicated by arrow B in FIG. 2B) moves pivot point 30 proximally, thereby forcing the jaws to close together. In alternative embodiments, tissue grabbing assembly 18 may comprise a grappling hook or fork, or plurality of needles coupled to the distal end of flexible tube 13.

[0055] Flexible tube 14 is affixed to and immovable within catheter 11, while flexible tube 13 is coupled to catheter 11 only via hinge 20. Accordingly, when control wire 19 is extended in the distal direction, flexible tube 13 is carried in the distal direction. When control wire 19 is retracted in the proximal direction, flexible tube remains stationary until jaws 28a and 28b close together, after which further retraction of control wire 19 by moving actuator 17 causes flexible tube 13 to buckle in bendable region 25, as described hereinafter.

[0056] Referring now to FIGS. 1 and 3A-3E, operation of apparatus 10 is described to create a tissue fold in a tissue wall of a GI lumen. In FIG. 3A, distal region 12

of catheter 11 is positioned within a patient's GI lumen transesophageally, and jaws 28a and 28b of tissue grabbing assembly 18 are opened by moving actuator 17 to the distal-most position on handle 16. As depicted in
5 FIG. 3B, actuator 17 may then be moved proximally until the jaws of tissue grabbing assembly 18 engage a portion of tissue wall **W** at contact point **P1**.

[0057] Referring to FIG. 3C, after the tissue wall has been engaged at contact point **P1**, flexible tube 13 is
10 urged proximally within catheter 11 by further proximal retraction of control wire 19 to stretch tissue wall **W** and create tissue fold **F**. During this movement of flexible tube 13, link 21 of hinge assembly 20 causes tissue grabbing assembly 18 to move from a position
15 distal to distal end 24 of flexible tube 14, to a position proximal of distal end 24 of flexible tube 14. Bendable sections 25 and 26 of flexible tubes 13 and 14, respectively, accommodate any lateral motion caused by operation of hinge assembly 20. Advantageously,
20 formation of fold **F** facilitates the penetration of the tissue wall by a needle and subsequent delivery of an anchor assembly, as described hereinafter.

[0058] Referring to FIG. 3D, additional proximal movement of actuator 17 causes flexible tubes 13 and 14
25 to buckle at bendable sections 25 and 26. Hinge assembly 20 transmits force applied to flexible tube 13 via control wire 19 and actuator 17 to the distal tip 24. Preferably, flexible tube 14 is configured so that distal tip 24 contacts, and is substantially perpendicular, to
30 tissue fold **F** at contact point **P2**. As illustrated in FIG. 3E, once tissue fold **F** is stretched across distal tip 24 of flexible tube 14, sharpened needle or obturator 34 may be extended from distal tip 24 of flexible tube 14 to pierce all four layers of the tissue wall **W**.

Sharpened needle or obturator 34 is inserted via inlet 35 to flexible tube 14 on handle 16 (see FIG. 1A).

[0059] As discussed above, the GI lumen comprises an inner mucosal layer, connective tissue, the muscularis layer and the serosa layer. To obtain a durable purchase, e.g., in performing a stomach reduction procedure, the staples or anchors used to achieve reduction of the GI lumen must engage at least the muscularis tissue layer, and more preferably, the serosa layer as well. Advantageously, stretching of tissue fold F across distal tip 24 permits an anchor to be ejected through both the muscularis and serosa layers, thus enabling durable gastrointestinal tissue approximation.

[0060] As depicted in FIG. 3E, after tissue fold F is stretched across distal tip 24 of flexible tube 14 to form contact point P2 with tissue wall W, needle 34 may be extended from distal tip 24 and through tissue fold F. Because needle 34 penetrates the tissue wall twice, it exits within the gastrointestinal lumen, thus reducing the potential for injury to surrounding organs. Once the needle has penetrated tissue fold F, an anchor assembly is ejected through distal tip 24 as described hereinbelow.

[0061] With respect to FIGS. 4A-4C, a first embodiment of an anchor assembly suitable for use with the apparatus of the present invention is described. Anchor assembly 36 comprises T-anchor assembly having distal rod 38a and proximal rod 38b connected by suture 39. The precise shape, size and materials of the anchors may vary for individual applications. In addition, the suture material also may vary for individual applications. By way of example, the suture material may consist of monofilament wire, multifilament wire or any other conventional suture material. Alternatively, suture 39

may comprise elastic material, e.g. a rubber band, to facilitate adjustment of the distance between the proximal and distal rods. Suture 39 extends through a pair of through-holes 40 in each rod, thereby forming a
5 loop. Alternatively, suture 39 may be attached to the rods via an eyelet or using a suitable adhesive. Preferably, through-holes 40 are located near the center of the rods 38a and 38b.

[0062] Referring to FIG. 4B, rods 38a and 38b may be
10 delivered through needle 34 (see FIG. 3E) using push rod 42. Push rod 42 is adapted to freely translate through flexible tube 14 and needle 34. Push rod 42 is preferably flexible, so that it may slide through bendable section 26 of flexible tube 14. In addition,
15 push rod 42 may include notch 43 near its distal end to facilitate grasping and tensioning suture 39 after anchor delivery.

[0063] During anchor delivery, the longitudinal axis of distal rod 38a is substantially parallel to the
20 longitudinal axis of needle 34. However, once distal rod 38a is ejected from needle 34, suture tension induces the rod to rotate approximately 90 degrees about its longitudinal axis, so that its longitudinal axis is substantially perpendicular to the longitudinal axis of
25 needle 35. This rotation of distal rod 38a prevents it from being pulled back through tissue wall W.

[0064] Referring to FIG. 4C, once rod 38a is ejected on the distal side of fold F, needle 35 is retracted and push rod 42 is used to eject rod 38b on the proximal side
30 of tissue fold F. Like distal rod 38a, tension in the suture causes proximal rod 38b to rotate about 90 degrees once it is ejected from the needle. Notch 43 in push rod 42 then may be employed to tighten suture 39 by any of a variety of mechanisms. Alternatively, suture 39 may

comprise an elastic material that dynamically tightens the rods against tissue fold **F**.

[0065] Referring now to FIG. 5A, according to other embodiments, the anchor assembly comprises a T-anchor assembly suitable to be disposed over obturator 50. More particularly, distal rod 38a includes through-hole 51 dimensioned for the passage of obturator tip 52, and obturator 50 is translatably inserted through flexible tube 14 via inlet 35 of handle 16 (see FIG. 1A).

10 Proximal rod 38b may be a solid rod that does not include a through-hole for passage of obturator 50. Alternatively, proximal rod 38b may include a through-hole for the passage of the obturator. Preferably, obturator tip 52 is sharpened to facilitate tissue

15 penetration.

[0066] With respect to FIG. 5B, once rod 38a is ejected on the distal side of fold **F**, it rotates into a position substantially parallel to tissue wall **W** and perpendicular to the longitudinal axis of the obturator.

20 Obturator 50 then is retracted and proximal rod 38b is ejected from flexible tube 14. More particularly, when flexible tube 14 is retracted from tissue wall **W**, proximal rod 38b is pulled through distal tip 24. Proximal rod 38b then rotates substantially 90 degrees as

25 it is ejected from flexible tube 14 so that rod 38b is urged against tissue wall **W**.

[0067] Referring to FIG. 6A, according to further embodiments, anchor assembly 55 comprises a T-anchor assembly similar to the embodiment depicted in FIG. 4A.

30 However, anchor assembly 55 includes fine wire tether 56 that may be twisted to maintain the tension between rods 38a and 38b.

[0068] With respect to FIG. 6B, a method of delivering anchor assembly 55 is described. Initially, distal rod

38a is delivered across both tissue walls using needle 34. The needle then is retracted to release distal rod 38a so that it engages the tissue wall. Next, needle 34 is retracted to release proximal rod 38b, so that it too rotates into engagement with the tissue wall. A proximal portion of the wire tether is captured by notch 43 of push rod 42 (see FIG. 4B), and the push rod is rotated to cause proximal rod 38b to clamp down on the tissue fold. Because wire tether 56 is twisted by rotation of push rod 42, it maintains the desired force on the tissue walls.

[0069] Referring now to FIGS. 7, a unidirectionally adjustable anchor assembly suitable for use with apparatus of the present invention is described. Anchor assembly 60 comprises distal anchor 62 and unidirectionally adjustable proximal anchor 64, which are connected by suture 39. Distal anchor 62 is translationally fixed with respect to suture 39. Such fixation may be achieved in a variety of ways. For example, as seen in FIG. 7A, distal anchor 62 may comprise a pair of through-holes 63, located near the center of anchor 62 and through which suture 39 is threaded and tied off at knot 65.

[0070] FIG. 7B provides alternative techniques for fixing the distal anchor. As seen in FIG. 7B(i), distal anchor 62 may comprise hollow tube **T** having opening **O**. A distal end of suture 39 is passed through opening **O** and formed into knot **K**, which is dimensioned such that it cannot pass through opening **O**, thereby fixing the distal anchor with respect to the suture. In order to facilitate formation of knot **K**, distal anchor 62 optionally may comprise distal opening **DO**, which is dimensioned such that knot **K** may pass therethrough. The distal end of suture 39 may be passed through distal

opening **DO**, knotted, and then pulled back within hollow tube **T** of anchor 62 until it catches at opening **O**.

[0071] A drawback of the fixation technique described with respect to FIG. 7B(i) is a risk of suture 39 being
5 torn or cut due to rubbing against opening **O**. In FIG. 7B(ii), hollow tube **T** comprises first end **E** to which is connected wire loop **L**, which may be formed, for example from a nickel-titanium alloy ("Nitinol"). Suture 39 passes through the wire loop before terminating at knot
10 **K**. Knot **K** is dimensioned such that it cannot pass back through the wire loop. Wire loop **L** directs suture 39 through opening **O**, thereby reducing rubbing of the suture against the opening and reducing a risk of tearing or cutting of suture 39.

15 [0072] FIG. 7B(iii) provides yet another alternative technique for fixing the distal anchor with respect to the suture. Distal anchor 62 again comprises hollow tube **T** having opening **O**. Rod **R** is disposed within tube **T**, and the ends of the tube may be either closed or crimped to
20 rod **R**, such that the rod is maintained within the tube. The distal end of suture 39 is threaded through opening **O**, around rod **R**, and back out opening **O**. The suture is then knotted at knot **K**, thereby fixing distal anchor 62 with respect to suture 39.

25 [0073] In addition to the techniques shown in FIGS. 7A and 7B, suture 39 alternatively may be fixed with respect to anchor 62 by other means, for example, via a knotted eyelet or via a suitable adhesive. Additional techniques will be apparent to those of skill in the art. While
30 anchor 62 is illustratively shown as a rod- or T-type anchor, any of a variety of anchors, per se known, may be used as distal anchor 62. Exemplary anchors are described in co-pending U.S. Patent Application Serial No. 10/612,170, filed July 1, 2003, which is incorporated

herein by reference in its entirety. Additional anchors are described hereinbelow with respect to FIGS. 17.

[0074] Referring again to FIG. 7A, adjustable proximal anchor 64 comprises outer cylinder 66 having first end 67a and second end 67b, as well as first opening 68a and second opening 68b. First and second openings 68 are preferably disposed near the center of cylinder 66 and approximately 180° apart. Anchor 64 further comprises first flexible rod 70a and second flexible rod 70b, both of which are disposed within outer cylinder 66 and coupled to first and second ends 67 of cylinder 66. Rods 70 may be formed, for example, from Nitinol or from a polymer, and may be separated from one another by small gap G. As with the previous anchor assemblies, the precise shape, size and materials of the anchors and suture may vary as required for specific applications.

[0075] As best seen in FIG. 7C, suture 39 passes from distal anchor 62 through first opening 68a of proximal anchor 64, around second flexible rod 70b, around first flexible rod 70a, between rods 70a and 70b, and out through second opening 68b. This suture winding provides a unidirectional adjustment capability that allows a length L of suture 39 disposed between distal anchor 62 and proximal anchor 64 to be shortened. However, the suture winding precludes an increase in length L. FIGS. 8 illustrate the mechanism of this unidirectional adjustment capability in greater detail. Optionally, suture 39 may be tied off proximal of anchor 64 at knot 69, thereby forming a proximal loop of suture to facilitate deployment and/or adjustment of anchor assembly 60.

[0076] In FIG. 8A, a proximally-directed force F_1 is applied to suture 39 proximal of adjustable anchor 64, while anchor 64 is held stationary or is advanced

distally. A portion of force F_1 is transferred through suture 39 to second flexible rod 70b, which causes rod 70b to bow, thereby increasing gap G and allowing suture 39 to freely pass between rods 70a and 70b and through proximal anchor 64, facilitating unidirectional adjustment. When anchor 64 is held stationary while suture 39 is retracted proximally, distal anchor 62 retracts proximally towards anchor 64. Alternatively, when anchor 64 is advanced distally while suture 39 is retracted proximally, distal anchor 62 either remains stationary or retracts proximally towards proximal anchor 64, depending upon a degree of distal advancement of proximal anchor 64. Regardless, length L of suture 39 disposed between anchors 62 and 64 is decreased, thereby unidirectionally adjusting a distance between the anchors.

[0077] In FIG. 8B, a distally-directed force F_2 is applied to suture 39 distal of adjustable anchor 64. Force F_2 may be applied, for example, by tissue compressed between anchors 62 and 64. Compressed tissue stores energy in a manner similar to a compression spring and seeks to push anchors 62 and 64 apart after unidirectional tightening. Force F_2 causes the loop of suture 39 around first and second rods 70 to tighten, thereby bowing both rods inward and closing gap G such that suture 39 is friction locked between first and second flexible rods 70. In this manner, the length L of suture between anchors 62 and 64 may be selectively decreased but cannot be increased.

[0078] As will be apparent to those of skill in the art, the magnitude of force required to unidirectionally adjust length L may be altered in a variety of ways. For example, a length, flexibility or diameter of rods 70 may be altered. Likewise, the elasticity or diameter of

suture 39 may be altered. Initial gap G may be increased or decreased. Furtherstill, the materials used to form rods 70 and suture 39 may be changed to alter material properties, such as coefficients of friction, and/or rods 70 or suture 39 may comprise a lubricious coating. Additional methods for varying the magnitude of force, a few of which are described hereinbelow with respect to FIGS. 9, will be apparent in view of this disclosure and are included in the present invention.

[0079] Referring now to FIGS. 9, alternative anchors 64 are described. In FIG. 9A, flexible rods 70 of proximal adjustable anchor 64' are rotated with respect to openings 68 (or vice versa). When utilizing the suture winding described in FIGS. 7 and 8, rotation of rods 70 up to 180° clockwise progressively increases friction when force is applied to anchors 62 and 64. The magnitude of the friction lock is increased when force is applied in the manner described with respect to FIG. 8B. However, friction is also increased when unidirectionally adjusting the length of suture between the proximal and distal anchors by applying force in the manner described with respect to FIG. 8A. Rotation of rods 70 more than about 180° clockwise would cause anchor 64' to friction lock regardless of which direction force were applied to suture 39, thereby negating the unidirectional adjustment capability. Counterclockwise rotation of rods 70 with respect to openings 68 would initially reduce friction during force application to suture 39 in either direction. It is expected that counterclockwise rotation in excess of about 90° would eliminate the friction lock described in FIG. 8B and allow bidirectional adjustment. Continued counterclockwise rotation beyond about 450° would reverse the directions of friction lock and unidirectional adjustment, while counterclockwise

rotation beyond about 720° would result in friction lock regardless of which direction force were applied to suture 39.

[0080] As discussed previously, openings 68 of
5 cylinder 66 of anchor 64 are preferably disposed
approximately 180° apart from one another. However, in
order to increase the friction lock force without
significantly increasing friction during unidirectional
adjustment, first opening 68a may be rotated
10 counterclockwise with respect to second opening 68b (or
vice versa), as seen with anchor 64'' of FIG. 9B. In
this manner, first opening 68a is no longer in line with
rods 70, while second opening 68b remains in line with
rods 70. When force F_1 is applied to anchor 64'', second
15 flexible rod 70b is able to bow outward and increase gap
 G , thereby facilitating unidirectional adjustment.
Likewise, when force F_2 is applied to the anchor, gap G is
closed more tightly upon suture 39, thereby increasing
the friction lock force. If first opening 68a
20 alternatively were rotated clockwise with respect to the
second opening, it is expected that the friction lock
force would be decreased.

[0081] In FIG. 9C, proximal adjustable anchor 64'''
comprises an alternative suture winding. Suture 39
25 passes from distal anchor 62 through first opening 68a of
anchor 64''', around second flexible rod 70b, around
first flexible rod 70a, back around second flexible rod
70b, between rods 70a and 70b, and out through second
opening 68b. As with the suture winding described with
30 respect to anchor 64 of FIGS. 7 and 8, the suture winding
illustrated in FIG. 9C provides a unidirectional
adjustment capability that allows a length L of suture 39
disposed between distal anchor 62 and proximal anchor
64''' to be shortened. However, this suture winding

precludes an increase in length L . Additional unidirectionally adjustable suture windings will be apparent to those of skill in the art.

[0082] With reference to FIGS. 10, an alternative unidirectionally adjustable anchor comprising three rods is described. Anchor assembly 80 comprises distal anchor 62 and proximal anchor 82. Unidirectionally adjustable proximal anchor 82 comprises outer cylinder 84 having first end 85a and second end 85b (not shown), as well as first opening 86a and second opening 86b. First and second openings 86 are preferably disposed near the center of cylinder 84 and approximately 180° apart. Anchor 82 further comprises first flexible rod 88a, second flexible rod 88b and third flexible rod 88c, all of which are disposed within outer cylinder 66 and coupled to first and second ends 85 of cylinder 64. Rods 88 are separated from one another by gaps G_1 and G_2 .

[0083] Suture 39 passes from distal anchor 62 through first opening 86a of proximal anchor 82, around first rod 88a, between first rod 88a and second rod 88b, between second rod 88b and third rod 88c, around third rod 88c, back to and around first rod 88a, and out through second opening 86b. As seen in FIG. 10A, when force F_1 is applied to suture 39, gaps G_1 and G_2 remain open, thereby facilitating unidirectional adjustment/shortening of length L of suture 39 disposed between distal anchor 62 and proximal anchor 82. As seen in FIG. 10B, when force F_2 is applied to suture 39, gaps G_1 and G_2 close down upon suture 39, thereby forming a friction lock that precludes an increase in length L of suture 39.

[0084] Referring now to FIGS. 11, an alternative three rod anchor assembly is described. The unidirectionally adjustable anchors described hereinabove with respect to FIGS. 7-10 all comprise rods disposed within a cylinder

having openings for passage of a suture. The openings act to center the suture with respect to the rods and can be used to alter magnitudes of force applied during adjustment and friction locking, as discussed previously.

5 However, such openings present a risk of tearing or cutting the suture as the suture slides through the openings.

[0085] As seen in FIGS. 11, anchor assembly 90 comprises distal anchor 62 and proximal anchor 92.

10 Unidirectionally adjustable proximal anchor 92 comprises first flexible rod 94a and second flexible rod 94b, as well as rigid rod 96, which is preferably larger in diameter than first and second rods 94. Flexible rods 94

15 are preferably fabricated from Nitinol or a polymer, while rigid rod 96 is preferably fabricated from stainless steel or a polymer. Alternative materials will be apparent to those of skill in the art.

[0086] Anchor 92 further comprises first outer cylinder 98a and second outer cylinder 98b, which are

20 crimped to the ends of first and second rods 94, and rigid rod 96. As an alternative to crimping, first and second cylinders 98 may each comprise an end cap (not shown) to which the rods are coupled. First and second cylinders 94 do not span a central portion of anchor 92.

25 Flexible rods 94 are separated from one another by gap G_1 , while rods 94 are separated from rigid rod 96 by gap G_2 .

[0087] Anchor 92 comprises three rods, but, unlike anchor 82 of FIGS. 10, suture 39 is only wrapped around two of them to achieve unidirectional adjustment. As

30 best seen in FIGS. 11B and 11C, the illustrative suture winding of anchor assembly 90 is similar to that described previously with respect to anchor assembly 60 of FIGS. 7 and 8. The break between first and second cylinders 98 acts to center suture 39 with respect to the

rods, as seen in FIG. 11A, while rigid rod 96 acts to stiffen and reduce rotation of anchor 92 as it directs suture 39 about flexible rods 94.

[0088] Suture 39 passes from distal anchor 62 to
5 proximal anchor 92, between rigid rod 96 and flexible rods 94, around second flexible rod 94b, around first flexible rod 94a, between rigid rod 96 and first flexible rod 94a, between flexible rods 94a and 94b, and out. As seen in FIG. 11A, when force F_1 is applied to suture 39,
10 flexible rods 94 are forced apart and gap G_1 widens while gap G_2 remains substantially constant, thereby allowing unidirectional adjustment of length L of suture 39 disposed between distal anchor 62 and proximal anchor 92. As seen in FIG. 11B, when force F_2 is applied to suture
15 39, gap G_1 closes down upon suture 39, thereby forming a friction lock that precludes an increase in length L of suture 39. Gap G_2 again remains substantially constant.

[0089] With reference to FIG. 12, an alternative unidirectionally adjustable anchor assembly comprising
20 pivots is described. Anchor assembly 100 comprises distal anchor 62 and proximal anchor 102. Unidirectionally adjustable proximal anchor 102 comprises outer cylinder 103 having first end 104a and second end 104b (not shown), as well as first opening 105a and
25 second opening 105b. First and second openings 105 are preferably disposed near the center of cylinder 103 and approximately 180° apart. Anchor 102 further comprises first rod or paddle 106a and second rod or paddle 106b, both of which are disposed within outer cylinder 103 and
30 coupled to the first and second ends of cylinder 103 by pins 107, which pass through pivot holes 108. In this manner, first and second paddles 106 are able to rotate about pivot holes 108. Paddles 106 may be formed, for example, from stainless steel or a polymer, and are

separated from one another by gap **G**. As with the previous anchor assemblies, the precise shape, size and materials of the anchors, as well as suture 39, may vary as required for specific applications.

5 **[0090]** Suture 39 illustratively passes from distal anchor 62 through first opening 105a of proximal anchor 102, around second paddle 106b, around first paddle 106a, between paddles 106a and 106b, and out through second opening 105b. The placement of pivot holes 108 ensures
10 that application of force **F**₁, as described hereinabove, causes paddles 106 to rotate apart from one another and expand gap **G**, thereby enabling unidirectional adjustment. Likewise, application of previously discussed force **F**₂ causes paddles 106 to rotate together, thereby closing
15 gap **G** and pinching suture 39 between the paddles in a friction lock. An increase in the magnitude of force **F**₂ serves to rotate paddles 106 together more tightly, thereby increasing the magnitude of the friction lock acting upon suture 39 between the paddles. In this
20 manner, unidirectional adjustment is achieved.

[0091] Referring now to FIG. 13, an alternative unidirectionally adjustable anchor assembly comprising spring material is described. Anchor assembly 110 comprises distal anchor 62 and proximal anchor 112.
25 Unidirectionally adjustable proximal anchor 112 comprises outer cylinder 113 having first end 114a and second end 114b (not shown), as well as first opening 115a and second opening 115b. First and second openings 115 are preferably disposed near the center of cylinder 113 and
30 approximately 180° apart. Anchor 112 further comprises first rod 116a and second rod 116b that are separated by gap **G**, as well as spring material 118, all of which are disposed within outer cylinder 113. Spring material 118 abuts rods 116, which preferably are substantially the

same length as cylinder 113, and may either move freely within cylinder 113 or may be coupled to the ends (not shown) of cylinder 113. Spring material 118 may also move freely within cylinder 113 or may be coupled to the cylinder, and comprises lumen 119 having a diameter that is preferably equal to or less than the diameter of suture 39. Spring material 118 may comprise, for example, a compressible biocompatible foam, which acts as a compression spring.

10 [0092] Suture 39 passes from distal anchor 62 to proximal anchor 112 through first opening 115a of cylinder 113, between rods 116, through lumen 119 of spring material 118, and out through second opening 115b. Lumen 119 snugly contacts suture 39 such that application of force F_1 causes friction between the suture and the spring material to compress the spring material against the wall of cylinder 114, thereby reducing a stress applied to rods 116 by spring material 118 and increasing gap G such that unidirectional adjustment of length L of suture 39 disposed between distal anchor 62 and proximal anchor 102 may proceed. Application of force F_2 stretches spring material 118 against rods 116, thereby increasing the stress applied to the rods by the spring material and closing gap G such that suture 39 is friction locked between rods 116.

25 [0093] With reference to FIGS. 14, alternative unidirectionally adjustable anchor assemblies comprising one-way valves are described. In FIG. 14A, anchor assembly 120 comprises distal anchor 62 and proximal anchor 122. Unidirectionally adjustable proximal anchor 122 comprises outer cylinder 124 having first and second ends 125a and 125b, as well as first opening 126a and second opening 126b. First and second openings 126 are preferably disposed near the center of cylinder 124 and

approximately 180° apart. Anchor 122 further comprises first inclined plane 128a and second inclined plane 128b, which are forced into apposition by compression springs 129a and 129b, thereby forming one-way valve V at the
5 junction of the two inclined planes. Inclined planes 128 and springs 129 are disposed within outer cylinder 124; springs 129 abut ends 125 of cylinder 124, as well as the ends of the inclined planes. Suture 39' comprises a plurality of knots or beads B adapted to actuate one-way
10 valve V.

[0094] Suture 39' passes from distal anchor 62 to proximal anchor 122 through first opening 126a of cylinder 124, between inclined planes 128, through one-way valve V, and out through second opening 126b.
15 Application of force F_1 to suture 39' causes a bead B to contact inclined planes 128 and gradually coax them apart by compressing springs 129, thereby opening valve V and allowing the bead to pass through the valve. Once the bead has passed through valve V, springs 129 force
20 inclined planes 128 back into apposition, thereby closing the valve. Continued application of force F_1 allows multiple beads to pass through the valve, which facilitates unidirectional adjustment of suture length L disposed between distal anchor 62 and proximal anchor
25 122. Application of force F_2 causes a bead B of suture 39' to impinge upon the proximal sides of inclined planes 128. However, force transferred to the planes by the bead is perpendicular to the direction required to compress springs 129 and urge planes 128 apart. As such,
30 the bead B impinging upon the proximal sides of planes 128 is not able to open one-way valve V and pass back through the valve in a distal direction, thereby ensuring only unidirectional adjustment, i.e. shortening, of the

length L of suture disposed between the proximal and distal anchors.

[0095] In FIG. 14B, an alternative unidirectionally adjustable anchor having a one-way valve is described. Anchor assembly 130 comprises distal anchor 62 and proximal anchor 132. Unidirectionally adjustable proximal anchor 132 comprises lumen 134 having cantilevered inclined plane 136 disposed therein, which forms one-way valve V . 'Zip-tie' fastener 138, having a plurality of inclined planes 139, connects proximal anchor 132 and distal anchor 62. The plurality of inclined planes 139 are disposed about 180° out of phase with inclined plane 136 of anchor 132.

[0096] Fastener 138 passes from distal anchor 62 to proximal anchor 132, through lumen 134 and past inclined plane 136. Inclined planes 139 of fastener 138 mesh with inclined plane 136 and bend or cantilever plane 136, such that planes 139 of fastener 138 may proximally pass one-way valve V when force F_1 is applied to the fastener, thereby enabling unidirectional adjustment of length L of fastener 138 disposed between the proximal and distal anchors. Conversely, when force F_2 is applied to the fastener, the proximal side of inclined plane 136 of anchor 132 abuts the distal side of an inclined plane 139 of fastener 138, and the fastener cannot be drawn distally through proximal anchor 132, nor can the length L of fastener disposed between the anchors be increased significantly.

[0097] Referring now to FIGS. 15, alternative unidirectionally adjustable anchor assemblies comprising a slipknot are described. In FIG. 15A, anchor assembly 140 comprises distal anchor 142 and proximal anchor 144. Through-holes 143a and 143b extend through distal anchor 142, while through-holes 145a and 145b extend through

proximal anchor 145. Preferably, through-holes 143 and 145 are located near the center of anchors 142 and 144, respectively.

[0098] The distal end of suture 39 passes through
5 through-hole 145a of proximal anchor 144 to distal anchor 142, where it passes through through-hole 143a and back through through-hole 143b. It then extends from distal anchor 142 back to proximal anchor 144, where it passes through through-hole 145b of the proximal anchor. The
10 distal end of suture 39 is tied off at unidirectional slipknot **S**, which is located proximal of anchor 144. FIG. 15B provides a detail view illustrating formation of slipknot **S**.

[0099] As will be apparent to those of skill in the
15 art, application of force F_1 causes suture 39 to slide through through-holes 143 and 145, and decrease the length **L** of suture 39 disposed between anchors 142 and 144. Suture 39 may readily pass through slipknot **S** in a proximal direction, thereby facilitating unidirectional
20 adjustment of length **L**. However, application of force F_2 tightens slipknot **S** and prohibits passage of suture 39 through the slipknot in a distal direction, thereby precluding an increase in length **L**.

[0100] FIG. 15C illustrates an alternative embodiment
25 of anchor assembly 140 wherein the slipknot is disposed within the proximal anchor. Anchor assembly 140' comprises distal anchor 142 and proximal anchor 144'. Proximal anchor 144' comprises hollow cylinder or tube 146 having distal openings 147a and 147b, and proximal
30 opening 148.

[0101] The distal end of suture 39 passes through proximal opening 148 into the interior of tube 146. It then passes through distal opening 147a of proximal anchor 144' to distal anchor 142, where it passes through

through-hole 143a and back through through-hole 143b.
Next, suture 39 extends from distal anchor 142 back to
proximal anchor 144', where it passes through distal
opening 147b into the interior of tube 146 of the
5 proximal anchor. The distal end of suture 39 is tied off
at unidirectional slipknot S, which is disposed within
tube 146 of anchor 144'. Anchor assembly 140' may be
unidirectionally adjusted in a manner similar to that
described hereinabove with respect to anchor assembly 140
10 of FIG. 15A.

[0102] FIGS. 7-15 illustrate anchor assemblies
comprising various mechanisms for achieving
unidirectional adjustment of the distance between the
proximal and distal anchors. These mechanisms have been
15 provided solely for the sake of illustration and should
in no way be construed as limiting. Additional
mechanisms for achieving unidirectional adjustment will
be apparent to those of skill in the art in view of this
disclosure and are included in the present invention.
20 Furthermore, a majority of the anchor assemblies of FIGS.
7-15 have been described with the distal anchor being
fixed relative to the suture, and the proximal anchor
being adjustable. However, it should be understood that
the distal anchor may alternatively be adjustable and the
25 proximal anchor may be fixed, and/or both anchors may be
unidirectionally adjustable, as with anchor assembly 140
of FIGS. 15.

[0103] With reference now to FIGS. 16, a bi-
directionally adjustable anchor assembly comprising a
30 locking mechanism is described. Anchor assembly 150
comprises distal anchor 62 and proximal anchor 152. As
seen in FIG. 16A, bi-directionally adjustable proximal
anchor 152 comprises outer cylinder 153 having first end
154a and second end 154b, as well as first opening 155a

and second opening 155b. First and second openings 155 are preferably disposed near the center of cylinder 153 and approximately 90° apart. Proximal anchor 152 further comprises tension spring 158 disposed within outer
5 cylinder 153.

[0104] As seen in FIG. 16B, suture 39 passes from distal anchor 62 to proximal anchor 152 through first opening 155a, around spring 158, and out through second opening 155b. Suture 39 moves freely about tension
10 spring 158 in either direction during application of force F_1 or force F_2 , thereby facilitating bi-directional adjustment of suture length L disposed between the proximal and distal anchors. However, as seen in FIG. 16C, simultaneous application of forces F_1 and F_2 with
15 sufficient magnitude causes suture 39 to force threads T of spring 158 apart, such that suture 39 is trapped between threads T and locked in position, thereby precluding further adjustment of suture length L .

[0105] The magnitude of forces required to actuate the
20 locking mechanism of proximal anchor 152 and lock suture 39 within threads T of spring 158 may be specified/altered in a variety of ways. For example, the angular spacing of openings 155 about outer cylinder 153 may be altered, the spring constant of spring 158 may be
25 specified, and/or spring 158 or suture 39 may comprise a lubricious coating. Additional techniques will be apparent to those of skill in the art. It is expected that simultaneous application of forces F_1 and F_2 will be encountered when anchor assembly 150 has been deployed
30 across a tissue fold and suture length L has been adjusted such that the tissue fold is compressed. A medical practitioner would then apply force F_1 , while the compressed tissue fold would apply force F_2 .

[0106] Although the anchor assemblies of FIGS. 10-16 have illustratively been described without knots or loops of suture or fastener disposed proximal of the proximal anchor (as seen, for example, with knot 69 on suture 39 of anchor assembly 60 in FIGS. 7 and 8) it should be understood that such loops or knots optionally may be provided in order to facilitate deployment and/or adjustment of the anchor assemblies. Additionally, the previously described anchor assemblies illustratively comprise distal rod- or T-type anchors. However, it should be understood that distal T-anchors have only been provided for the sake of illustration. The distal anchors (as well as the proximal anchors) may comprise any of a variety of anchors, per se known. Exemplary anchors are described in co-pending U.S. Patent Application Serial No. 10/612,170, filed July 1, 2003, which is incorporated herein by reference in its entirety. Additional anchors are described hereinbelow with respect to FIGS. 17.

[0107] Referring to FIG. 17A, articulating anchor 160 includes semi-cylindrical base 161, rod 162 and suture 39. Rod 162 rotates about pivot point 163 (as indicated by arrow 164) between an expanded position (shown in FIG. 7A) and a reduced profile position, wherein rod 162 pivots within the semi-cylindrical base 161. Articulating anchor 160 may be delivered through a tissue fold using needle 34 described hereinabove with respect to FIG. 3E. Preferably, articulating anchor 160 is biased in the expanded position so that it automatically expands once it is ejected from the needle.

[0108] With respect to FIGS. 17B and 17C the anchors of the present invention also may comprise one or more oblong bodies connected by at least one suture. In FIG. 17B, anchor 165 comprises elliptical ring 166 having

sutures 39 attached at substantially opposite sides of the ring. In FIG. 17C, anchor 168 comprises angle bracket 169 having a pair of through-holes 170 for suture 39. In FIG. 17D, anchor 171 comprises oblong bead 172
5 having a pair of through-holes 173 for suture 39. All three anchors 165, 168 and 171 (as well as the T-anchors described previously) have a first dimension (e.g., width) that is substantially larger than a second dimension (e.g., height). This dimensional difference
10 necessitates that anchors 165, 168 and 171 be inserted within needle (e.g., needle 34 of FIG. 3E) in a particular orientation. Once the anchor is ejected through a tissue wall, tension on suture 39 forces the anchor to rotate so that it cannot be pulled back through
15 the tissue wall. As will be understood by those of skill in the art, numerous other anchors may be employed without departing from the scope of the present invention.

[0109] Referring now to FIG. 18A, an alternative
20 embodiment of apparatus for forming a tissue fold, constructed in accordance with the principles of the present invention, is described. Apparatus 175 comprises treadmill assembly 176 disposed at distal tip 174 of flexible tube 177. Flexible tube 177 is configured to be
25 inserted through a patient's mouth, esophagus and into the stomach. Treadmill assembly 176 comprises conveyor 180 that circles around a pair of hubs 181a and 181b. Hubs 181a and 181b rotate about axles 182a and 182b, respectively, and are interconnected by bracket 183. A
30 plurality of barbs or needles 185 is disposed at substantially regular intervals around the circumference of conveyor 180.

[0110] Flexible tube 177 preferably includes a plurality of through-wall slots 186 to enhance

flexibility of the tube, yet maintain torqueability.
Preferably, flexible tube 177 is made from stainless
steel with an etched or laser-cut slot pattern.
Preferably, the slot pattern is a sinusoidal repeating
5 pattern of slots perpendicular to the longitudinal axis
of the tube.

[0111] Referring to FIGS. 18 and 19, transmission of
motive force to treadmill assembly 176 is described. In
particular, drive shaft 202 disposed within flexible tube
10 177 is coupled to a manual knob or motor located at the
proximal end of the catheter. The distal tip of drive
shaft 202 is provided with beveled gear 203 that meshes
with beveled gear 204 provided on axle 182b.

Accordingly, rotation of beveled gear 203 is transmitted
15 to beveled gear 204, thereby causing axle 182b to rotate.
Axle 182b in turn rotates hub 181b, actuating conveyor
180. Reversing the rotation of drive shaft 202 reverses
the direction of conveyor 180.

[0112] Referring again to FIGS. 18A-18D, a method of
20 forming a gastrointestinal tissue fold **F** using apparatus
175 is described. In FIG. 18A, flexible tube 177 is
positioned transesophageally so that treadmill assembly
176 contacts tissue wall **W**. Preferably, contact should
be made at an angle relative to the tissue wall **W**. For
25 example, an angle of approximately 45 degrees is depicted
in FIG. 8A, while many other angles may be used without
departing from the scope of the present invention.

[0113] When treadmill assembly 176 contacts tissue
wall **W**, needle 185 engages the tissue at contact point **P1**
30 as the needle moves around distal hub 181a. As depicted
in FIG. 18B, as the needle moves away from distal hub
181a, tissue wall **W** is pulled towards proximal end 181b,
thereby forming a small tissue fold **F**. As the treadmill
assembly continues to turn, subsequent needles 185 engage

the tissue wall so that it becomes securely engaged to treadmill assembly 176 along the length of conveyor 180.

[0114] As depicted in FIG. 18C, once tissue wall **W** is securely engaged to treadmill assembly 176, distal end 5 174 of flexible tube 177 may be articulated in bendable section 190, thereby moving treadmill assembly 176 away from tissue wall **W**. The articulation of flexible tube 177 may be accomplished using a control wire and actuator disposed at the proximal end of the catheter, as 10 previously described with respect to the embodiment of FIGS. 1. By moving the treadmill assembly away from tissue wall **W**, additional tissue is pulled proximally and tissue fold **F** becomes elongated.

[0115] In FIG. 18D, tissue fold **F** is stretched across 15 bendable section 190 of flexible tube 177 to create contact point **P2**. This permits a sharpened needle or obturator to be extended through one of slots 186 of bendable section 190 and across all four layers of the tissue wall **W**. Advantageously, stretching of tissue fold 20 **F** across bendable section 190 permits an anchor to be ejected through both the muscularis and serosa layers, thus providing a durable foundation for gastrointestinal tissue approximation. For example, needle 192 may be extended through slot 186 in bendable section 190, and 25 through the base of tissue fold **F**, and an anchor assembly (such as described with respect to any of FIGS. 4-17) may be ejected from needle 192 to secure the fold.

Alternatively, an obturator (such as described with respect to FIGS. 5A and 5B) may be used to pierce the 30 tissue fold at contact point **P2** and deliver the anchor assembly. Treadmill assembly 176 may be disengaged from tissue wall **W** by reversing the rotation of proximal hub 181b.

[0116] Referring now to FIG. 20A, a further alternative embodiment of apparatus for forming a tissue fold in accordance with the principles of the present invention is described. Apparatus 200 comprises tissue grabbing assembly 18' coupled to the distal end of a flexible tube 177', such as described with respect to the embodiment of FIGS. 18. Flexible tube 177' preferably includes a plurality of through-wall slots 186' to enhance flexibility of the tube, yet maintain torqueability. In addition, flexible tube 177' may be made from stainless steel with an etched or laser-cut slot pattern, such as a sinusoidal repeating pattern of slots perpendicular to the longitudinal axis of the tube.

[0117] Tissue grabbing assembly 18' is similar to that described with respect to the embodiment of FIGS. 1, and comprises a pair of jaws 28a', 28b' arranged to rotate about pivot point 29' between an open configuration and a closed configuration. Each of jaws 28a', 28b' preferably includes sharpened teeth 33' disposed near its distal end to facilitate grasping tissue wall W.

[0118] With respect to FIG. 20A, tissue grabbing assembly 18' is positioned transesophageally adjacent to tissue wall W and jaws 28a', 28b' are moved to the open position. Tissue grabbing assembly 18' then is moved into contact with tissue wall W. As depicted in FIG. 20B, tissue grabbing assembly 18' is used to grab the tissue wall at a first contact point P1. After capturing a portion of tissue wall W within jaws 28a', 28b', flexible tube 177' is urged proximally to stretch tissue wall W and create tissue fold F.

[0119] Referring to FIG. 20C, once tissue fold F is formed, the distal end of flexible tube 177' is articulated about bendable section 190' to move tissue grabbing assembly 18' away from tissue wall W.

Articulation of flexible tube 177' may be controlled using an actuator disposed at the proximal end of the catheter, thus causing tissue fold **F** to become elongated.

[0120] In FIG. 20D, tissue fold **F** is shown stretched
5 across bendable section 190' so that a sharpened needle or obturator may be extended from one of slots 186' in bendable section 190' and across all four layers of the tissue wall **W**. Needle 192' then may be extended from slot 186' in bendable section 190' through contact point
10 **P2** and tissue fold **F**. An anchor assembly (e.g., as described with respect to any of FIGS. 4-17) then may be ejected from needle 192' to secure the fold.
Alternatively, an obturator (e.g., as described with respect to FIGS. 5A and 5B) may be used to pierce the
15 tissue fold at contact point **P2** and deliver the anchor assembly.

[0121] With reference now to FIGS. 21, an anchor delivery system adapted for use with the adjustable anchor assemblies of FIGS. 7-17 is described. In FIGS.
20 21, the anchor delivery system is illustratively shown in use with anchor assembly 60 of FIGS. 7, but this should in no way be construed as limiting. Also, the delivery system of FIGS. 21 may be used in conjunction with apparatus for forming a tissue fold, such as apparatus
25 10, 175 and 200 described previously, in order to anchor the tissue fold; or may be used for any other application, or in conjunction with any other apparatus, requiring delivery of an anchor assembly.

[0122] In FIG. 21A, a distal region of anchor delivery
30 system 250 is disposed adjacent tissue fold **F** in tissue wall **W**. Anchor delivery system 250 comprises flexible delivery tube 252 having lumen 253. Flexible delivery tube 252 may be configured for insertion through a patient's mouth and esophagus into a gastrointestinal

lumen, such as the stomach. Lumen 253 of delivery tube 252 preferably has a diameter of less than about 3cm, and even more preferably has a diameter of about 2.5cm. Flexible delivery tube 252 preferably includes a

5 plurality of through-wall slots 254 to enhance flexibility of the tube, yet maintain torqueability. Slots 254 may form bendable section 255. Preferably, flexible delivery tube 252 is made from stainless steel with an etched or laser-cut slot pattern. The slot

10 pattern is preferably a sinusoidal repeating pattern of slots perpendicular to the longitudinal axis of the tube. [0123] Anchor delivery system 250 further comprises delivery needle 260. Needle 260 preferably has a length of less than 2cm, and even more preferably has a length

15 of about 1.5cm. Needle 260 preferably comprises sharpened distal tip 262, lumen 264, slot 266 extending proximally from distal tip 262, and proximal eyelet 268. [0124] Lumen 264 of needle 260 is dimensioned such that a distal anchor may be disposed therein. As

20 discussed previously, anchor delivery system 250 is illustratively described in conjunction with anchor assembly 60 of FIGS. 7. In FIG. 21A, distal anchor 62 is disposed within lumen 264 of needle 260. Suture 39 passes through slot 266 of the needle as the suture

25 extends from distal anchor 62 to proximal anchor 64. Needle 260 preferably is disposed within lumen 253 of flexible delivery tube 252 distal of bendable section 255, while proximal anchor 64 preferably is disposed within delivery tube 252 proximal of bendable section

30 255. [0125] In this arrangement, distal anchor 62 may be deployed through needle 260 while the bendable section is actuated or bent, e.g., when anchor delivery system 250 is used in conjunction with previously described

plication apparatus. Proximal anchor 64 subsequently may be advanced through bendable section 255 after the bendable section has once again been straightened. The distance, or length, of suture 39 extending between

5 distal anchor 62, which is disposed distal of the bendable section, and proximal anchor 64, which is disposed proximal of the bendable section, is preferably greater than or equal to about 2cm, and is even more preferably greater than or equal to about 4cm.

10 [0126] Needle 260 is proximally coupled to needle pushrod 270, which facilitates translation of the needle beyond a distal end of flexible delivery tube 252. Needle pushrod 270 extends to a control actuator disposed at a proximal end of anchor delivery system 250 (not

15 shown). Pushrod 270 optionally may be spring-loaded (not shown), for example, to facilitate puncture of tissue wall W and passage of needle 260 through tissue fold F.

[0127] Anchor delivery system 250 further comprises anchor pushrod 280, which is removably disposed through

20 eyelet 268 of needle 260, and is configured to eject distal anchor 62 from lumen 264 of needle 260. As with needle pushrod 270, anchor pushrod 280 extends to a control actuator disposed at a proximal end of anchor delivery system 250 (not shown). The actuators

25 controlling pushrods 270 and 280 are preferably at least partially coupled so that relative motion between the two pushrods can be limited and/or eliminated, as needed. Pushrod 280 passes through the proximal loop of suture formed by knot 69 on suture 39, such that the suture loop

30 is threaded between needle pushrod 270 and anchor pushrod 280. This facilitates unidirectional adjustment of the length of suture disposed between distal anchor 62 and proximal anchor 64, as described hereinbelow.

[0128] In FIG. 21B, pushrods 270 and 280 are simultaneously distally advanced with sufficient force, e.g., via spring-loading, such that sharpened distal tip 262 of needle 260 pierces tissue wall W and is advanced across fold F. Bendable section 255 of flexible delivery tube 252 optionally may be bent during advancement of the needle, as described previously with respect to the plication apparatus (see FIG. 3E). Anchor pushrod 280 is then advanced distally with respect to needle pushrod 270 and needle 260, such that it abuts distal anchor 62 and ejects the anchor from lumen 264 of needle 260 on the distal side of tissue fold F, as seen in FIG. 21C. Suture 39 likewise is ejected from slot 266 and disposed across fold F.

[0129] During delivery, the longitudinal axis of distal anchor 62 is substantially parallel to the longitudinal axis of needle 260. However, once anchor 62 has been ejected from needle 260, suture tension induces the anchor to rotate approximately 90° about its longitudinal axis, so that its longitudinal axis is substantially perpendicular to the longitudinal axis of needle 260. This rotation of distal anchor 62 prevents it from being pulled back through tissue wall W. One or both ends of anchor 62 may be flared outward (not shown) to facilitate such rotation upon contact with the tissue wall.

[0130] In FIG. 21D, anchor pushrod 280 is retracted proximally within lumen 264 of needle 260, the needle is retracted within flexibly delivery tube 252 via pushrod 270, and then delivery system 250 is retracted proximally across tissue fold F. Distal anchor 62 is disposed on the distal side of the tissue fold, suture 39 extends through the fold, and proximal anchor 64 is disposed on the proximal side of the fold within delivery tube 252.

If bendable section 255 were flexed during deployment of distal anchor 62 (see FIG. 3E), it is straightened to facilitate delivery of the proximal anchor.

[0131] Delivery tube 252 is then retracted proximally
5 with respect to pushrods 270 and 280, causing needle 260 to exit lumen 253 of the delivery tube on the proximal side of tissue fold **F**, thereby providing space for proximal anchor 64 to exit the lumen. Next, delivery tube 252 or the full delivery system 250 is retracted,
10 such that proximal anchor 64 is ejected from delivery tube lumen 253, as seen in FIG. 21E. Delivery tube 252 is then re-advanced and/or pushrods 270 and 280 are simultaneously retracted, such that needle 260 is repositioned within lumen 253 of the delivery tube.

15 [0132] Flexible delivery tube 252 is advanced with respect to needle 260, such that it pushes proximal anchor 64 distally. The proximal suture loop formed by knot 69 on suture 39 catches against the proximal end of needle 260 and anchor pushrod 280, which pulls distal
20 anchor 62 taut against tissue fold **F**, as seen in FIG. 21F. Continued advancement of delivery tube 252 unidirectionally adjusts, i.e. shortens, length **L** of suture 39 disposed between distal anchor 62 and proximal anchor 64, while forcing proximal anchor 64 against the
25 tissue fold and firmly anchoring the fold between the proximal and distal anchors.

[0133] Once length **L** has been adjusted such that anchor assembly 60 firmly anchors tissue fold **F** in position, anchor pushrod 280 may be retracted proximally
30 with respect to needle pushrod 270 and needle 260, such that the distal end of anchor pushrod 280 is proximally retracted through eyelet 268 and out of needle 260. As seen in FIG. 21G, the suture loop formed by knot 69 on suture 39 slips off the distal end of anchor pushrod 280,

removing anchor assembly 60 from anchor delivery system 250 and allowing the anchor delivery system to be removed from the patient.

[0134] Delivery system 250 optionally may comprise cutting apparatus (not shown) for removing the portion of suture extending proximally of proximal anchor 64 post-adjustment. Alternatively, secondary apparatus may be provided to remove such proximal length of suture. As yet another alternative, the unneeded length of suture may be left within the patient post-procedure.

[0135] In order to decrease the number of steps required to deliver and adjust anchor assembly 60, once distal anchor 62 has been deployed, as in FIG. 21C, the entire anchor delivery system 250 may be retracted proximally, such that needle 260 is retracted across tissue fold **F** while still disposed outside of delivery tube lumen 253. This is in contrast to the method described with respect to FIG. 21D, wherein the needle is disposed within the delivery tube prior to retraction across the tissue fold. Continued proximal retraction of anchor delivery system 250 or delivery tube 252 deploys proximal anchor 64 from delivery tube lumen 253. Anchor assembly 60 then may be unidirectionally adjusted, as described previously.

[0136] As will be apparent to those of skill in the art, when anchor delivery system 250 is used in conjunction with previously described apparatus 10, 175 or 200, to place an anchor assembly across fold **F** formed by said apparatus, flexible delivery tube 252 may either comprise or be advanced through flexible tube 14, 177 or 177', of apparatus 10, 175 or 200, respectively. Likewise needle 260 may comprise needle 34, 92 or 92', of apparatus 10, 175 or 200, respectively. Needle 260 may alternatively comprise obturator 50 of FIGS. 5.

[0137] Referring now to FIGS. 22, an alternative anchor delivery system is described. As with anchor delivery system 250 of FIGS. 21, anchor delivery system 300 of FIGS. 22 is adapted for use with the adjustable anchor assemblies of FIGS. 7-17. In FIGS. 22, the anchor delivery system 300 is illustratively shown in use with anchor assembly 60 of FIGS. 7, but this should in no way be construed as limiting. Also, delivery system 300 may be used in conjunction with apparatus for forming a tissue fold, such as apparatus 10, 175 and 200 described previously, in order to anchor the tissue fold; or may be used for any other application, or in conjunction with any other apparatus, requiring delivery of an anchor assembly.

[0138] FIG. 22A illustrates a distal region of anchor delivery system 300. System 300 comprises flexible delivery tube 302 having lumen 303. Flexible delivery tube 302 may be configured for insertion through a patient's mouth and esophagus into a gastrointestinal lumen, such as the stomach. Flexible delivery tube 302 preferably includes a plurality of through-wall slots 304 to enhance flexibility of the tube, yet maintain torqueability. Slots 304 may form bendable section 305. Preferably, flexible delivery tube 302 is made from stainless steel with an etched or laser-cut slot pattern. The slot pattern is preferably a sinusoidal repeating pattern of slots perpendicular to the longitudinal axis of the tube.

[0139] Flexible delivery tube 302 further comprises end region 306, which is coupled to anchor tube 307 having lumen or bore 308. As best seen in FIG. 22B, lumen 308 of anchor tube 307 communicates with lumen 303 of delivery tube 302 via through-slot 309. Proximal anchor 64 is disposed within anchor tube 307, while

distal anchor 62 is disposed within needle 260', which sits within delivery tube 302.

[0140] Suture 39 passes out of needle 260' from distal anchor 62 through slot 266'. It then crosses from flexible delivery tube 302 to anchor tube 307 via through-slot 309. After passing through proximal anchor 64, suture 39 is passed back to delivery tube 302 via the through-slot, and is threaded around anchor pushrod 280', such that the loop of suture formed by knot 69 on suture 39 is disposed between needle pushrod 270' and anchor pushrod 280'.

[0141] Needle 260', needle pushrod 270' and anchor pushrod 280' are substantially the same as needle 260 and pushrods 270 and 280, respectively, which are described hereinabove with respect to anchor delivery system 250 of FIGS. 21. Furthermore, anchor assembly 60 may be delivered from and adjusted by anchor delivery system 300 in a manner similar to that described hereinabove with respect to system 250.

[0142] In FIG. 22A, anchor tube 307 of anchor delivery system 300 is illustratively shown as a relatively short tube having lumen or bore 308 adapted for disposal of proximal anchor 64 therein. However, it should be understood that anchor tube 307, lumen 308 and/or through-slot 309 alternatively may extend all or part of the way to a proximal end of flexible delivery tube 302 of delivery system 300. Advantageously, such an arrangement facilitates loading of anchor assembly 60 from a proximal end of the anchor delivery system and may simplify manufacturing of the system.

[0143] Anchor delivery system 300 illustratively has been described with a single anchor assembly 60 disposed therein. However, it should be understood that a plurality of anchor assemblies may be loaded within

delivery system 300, thereby facilitating delivery of multiple anchor assemblies across different points of a tissue fold, across different (e.g., adjacent) tissue folds, or across other tissue structures. The plurality
5 of distal anchors 62 preferably are loaded within needle 262' of flexible delivery tube 302, while the plurality of proximal anchors 64 preferably are loaded within lumen 308 of anchor tube 307.

[0144] An advantage of anchor delivery system 300, as
10 compared to system 250 of FIGS. 21, is that both the proximal and distal anchors are located distal of the bendable section of the delivery tube during delivery. This reduces an initial length of suture that must be disposed between the anchors, thereby reducing a length
15 of unneeded suture extending proximally of the proximal anchor post-delivery and adjustment. It also simplifies delivery by allowing both the proximal and distal anchors to be delivered while the bendable section of the delivery tube is bent. Additionally, placement of the
20 proximal anchor in a separate anchor tube eliminates a need to eject the needle from the flexible delivery tube on the proximal side of a tissue fold in order to deploy the proximal anchor, thereby reducing a risk of accidental tissue puncture with the needle.

25 [0145] With reference to FIG. 23, another alternative anchor delivery system is described. As with anchor delivery systems 250 and 300 of FIGS. 21 and 22, respectively, anchor delivery system 400 of FIG. 23 is adapted for use with the adjustable anchor assemblies of
30 FIGS. 7-17. Anchor delivery system 400 is illustratively shown in use with anchor assembly 60 of FIGS. 7, but this should in no way be construed as limiting. Also, delivery system 400 may be used in conjunction with apparatus for forming a tissue fold, such as apparatus

10, 175 and 200 described previously, in order to anchor the tissue fold; or may be used for any other application, or in conjunction with any other apparatus, requiring delivery of an anchor assembly.

5 [0146] FIG. 23 illustrates a distal region of anchor delivery system 400. System 400 comprises flexible delivery tube 402 having lumen 403. Flexible delivery tube 402 may be configured for insertion through a patient's mouth and esophagus into a gastrointestinal
10 lumen, such as the stomach. Flexible delivery tube 402 preferably includes a plurality of through-wall slots to enhance flexibility of the tube, yet maintain torqueability. The slots may form bendable section 405.

[0147] Anchor delivery system 400 further comprises
15 delivery needle 260'', which is disposed within lumen 403 of flexible delivery tube 402 distal of bendable section 405 during delivery. As discussed previously, anchor delivery system 400 is illustratively described in conjunction with anchor assembly 60 of FIGS. 7. Needle
20 260'' preferably has a length sufficient for both distal anchor 62 and proximal anchor 64 of anchor assembly 60 to be disposed therein; for example, needle 260'' preferably has a length of less than about 5cm, and even more preferably has a length of about 3cm. Except for an
25 increase in length, needle 260'' is substantially the same as needle 260 of FIGS. 21.

[0148] In FIG. 23, both distal anchor 62 and proximal anchor 64 are disposed within lumen 264'' of needle 260''. Suture 39 passes through and back through slot
30 266'' of the needle as the suture extends from distal anchor 62 to proximal anchor 64. Alternatively the length of suture between the proximal and distal anchors may be disposed within the needle during delivery. Advantageously, both the proximal and distal anchors of

anchor assembly 60 may be deployed through needle 260'' while bendable section 405 is actuated or bent, e.g., while anchor delivery system 400 is used in conjunction with previously described plication apparatus.

5 [0149] Needle 260'' is proximally coupled to flexible needle pushtube 420, which facilitates translation of the needle beyond a distal end of flexible delivery tube 402. As will be apparent to those of skill in the art, needle 260'' and needle pushtube 420 optionally may be
10 manufactured as a single piece. Needle pushtube 420 comprises lumen 422, as well as skive 424 that communicates with lumen 422. Needle pushtube 420 extends to a control actuator (not shown), which may be spring-loaded, disposed at a proximal end of anchor delivery
15 system 400.

[0150] Anchor pushrod 280'', which is substantially the same as anchor pushrod 280 described previously, is removably disposed within lumen 422 of needle pushtube 420 distal of skive 424. As with pushtube 420, anchor
20 pushrod 280'' extends to a control actuator (not shown) disposed at a proximal end of the anchor delivery system. Suture 39 proximally extends from proximal anchor 64 through slot 266'' of needle 260'', through skive 424 and within lumen 422 of needle pushtube 420, around anchor
25 pushrod 280'' and out through skive 424 to knot 69. The proximal loop of suture formed by knot 69 is trapped around pushrod 280'' and within lumen 422 of the needle pushtube, thereby facilitating unidirectional adjustment of the length of suture disposed between distal anchor 62
30 and proximal anchor 64. As an alternative to the proximal loop of suture, knot 69 may be formed on the proximal end of suture 39, such that the knot is trapped between anchor pushtube 280'' and needle pushrod 420 (see knot K of FIG. 24).

[0151] Anchor assembly 60 may be delivered from and adjusted by anchor delivery system 400 in a manner similar to that described hereinabove with respect to system 250 of FIGS. 21, with a few alterations.

5 Specifically, during deployment of distal anchor 62, anchor pushrod 280'' is advanced against proximal anchor 64, which in turn advances in-line distal anchor 62. The pushrod is advanced a sufficient distance with respect to needle 260'' to eject the distal anchor from needle lumen 10 264'', but not so far as to also prematurely eject proximal anchor 64. Motion limitation apparatus may be provided to ensure that the distal anchor is not prematurely ejected. Exemplary motion limitation apparatus is described hereinbelow with respect to FIG. 15 24; additional apparatus, per se known, will be apparent.

[0152] In order to eject proximal anchor 64 from lumen 264'' of needle 260'', either the needle is retracted until length L of suture 39 disposed between the proximal and distal anchors is pulled taut and pulls the proximal 20 anchor out of the needle lumen, or anchor pushrod 280'' is advanced a sufficient distance within the lumen of needle 260'' to eject the proximal anchor from the lumen (or a combination thereof). Additionally, in order to release anchor assembly 60 from anchor delivery system 25 400 post-delivery and adjustment, anchor pushrod 280'' is retracted proximal of skive 424 such that the loop of suture 39 formed by knot 69 is no longer trapped within lumen 422 of needle pushrod 420.

[0153] A significant advantage of anchor delivery 30 system 400, as compared to system 250 of FIGS. 21, is that both the proximal and distal anchors are disposed distal of bendable section 405 of flexible delivery tube 402. A significant advantage of anchor delivery system 400, as compared to system 300 of FIGS. 22, is that both

the proximal and distal anchors are disposed within needle 260'', thereby eliminating a need for an anchor tube and reducing the profile of the system.

[0154] Referring now to FIG. 24, an alternative embodiment of anchor delivery system 400 is described comprising motion limitation apparatus. Anchor delivery system 400' is substantially the same as system 400, except that needle pushrod 420' comprises two skives: motion limitation skive 430 and unidirectional adjustment skive 432, both of which communicate with lumen 422' of the needle pushrod. Suture 39 proximally extends from proximal anchor 64, through motion limitation skive 430 and within lumen 422' between anchor pushrod 280'' and needle pushtube 420'. Suture 39 exits skive 430 and is tied off at motion limitation knot K, which is trapped at skive 430 by anchor pushrod 280''. Suture 39 then continues proximally to unidirectional adjustment skive 432 and the proximal loop of suture formed by knot 69, which is trapped at skive 432 around pushrod 280''.

[0155] A length of suture extending between proximal anchor 64 and knot K is specified such that distal anchor 62 may exit lumen 264'' of needle 260'', but proximal anchor 64 cannot while knot K is trapped at skive 430 by anchor pushrod 280''. For example, during delivery of anchor assembly 60 across a tissue fold, advancement of pushrod 280'' advances proximal anchor 64, which in turn advances in-line distal anchor 62 until the distal anchor is ejected from needle lumen 264'' on the distal side of the tissue fold. Knot K limits a distance anchor pushrod 280'' may be advanced and ensures that proximal anchor 64 is not prematurely deployed.

[0156] Once anchor delivery system 400' is again disposed on the proximal side of the tissue fold, anchor pushrod 280'' is retracted proximal of motion limitation

skive 430, thereby allowing knot K to escape from skive 430 and facilitating deployment of proximal anchor 64. Proximal anchor 64 may be deployed by either retracting needle 260'' until the length of suture between the two
5 anchors is pulled taut and pulls the proximal anchor out of the needle, or by re-advancing pushrod 280'' to push the proximal anchor out of the needle.

[0157] The anchor assembly may then be unidirectionally adjusted via the suture loop trapped at
10 skive 232, as described previously. After adjustment has been completed, anchor pushrod 280'' is retracted proximal of unidirectional adjustment skive 432, thereby allowing the loop of suture formed by knot 69 of suture 39 to escape from skive 432. A significant advantage of
15 anchor delivery system 400', as compared to system 400 of FIG. 23, is that motion limitation skive 430 reduces a risk of premature deployment of proximal anchor 64.

[0158] Although preferred illustrative embodiments of the present invention are described hereinabove, it will
20 be apparent to those skilled in the art that various changes and modifications may be made thereto without departing from the invention. It is intended in the appended claims to cover all such changes and modifications that fall within the true spirit and scope
25 of the invention.
